

Lunar Geotechnical Site Characterization and Preparation for Exploration and Infrastructure Development

Jared Long-Fox

University of Central Florida – Department of Physics

LSIC E&C Monthly Meeting – July 26, 2023

UCF

Introduction

- Sustainable lunar permanence relies on:
 - Safe and efficient interactions with planetary surfaces (landing, roving, infrastructure development)
 - Utilization of local resources
- Regolith will be the primary feedstock for infrastructure development and *in situ* resource utilization (ISRU)
 - Site-specific physical and chemical properties that are very different from Earth
 - Extreme environment - reduced gravity, no atmosphere (and related effects), and limited energy resources

Image credit: NASA

The Need for Site Characterization and Preparation

- Terrestrial construction requires site characterization and specific preparation methods to bring the site into acceptable specs → need same for the Moon
 - Need to define “acceptable” for the lunar case
- Need to characterize *in situ* physical properties
 - Unlike what we deal with on Earth
 - Extreme environment
 - Site specific variations
- Should use simple, standard exploration tools and tests whenever possible
 - Borrow from terrestrial studies as able
 - Minimize mass → cheaper and more efficient launches and operations

Experimental Hardware

- COLDArm testing campaign at NASA KSC Swamp Works
 - Ground interaction data being collected using COLDArm geotechnical scoop
 - Force-torque sensor on UR10 arm
 - LHS-1B simulant

Site Characterization Experiments

- **Angle of Repose**
 - Provides a first-order look at the strength of the material you are working with
- **Pressure-Sinkage**
 - Provides information on bearing capacity and trafficability
 - Bernstein (1913), Bekker (1969), and Reece (1965)
- **Shear**
 - A fundamental quantity to characterize (e.g., Mohr-Coulomb relationship) – shear strength plays a part in nearly all other mechanical properties of regolith (including AoR)
- **Excavation**
 - Convolution of horizontal and vertical forces acting on regolith
 - Able to learn physical properties based on forces observed during excavation (more on this soon!)
- **Materials**
 - Need high-fidelity lunar regolith simulants

Site Characterization: Angle of Repose

- Gives insights into the high-level physical properties of regolith
 - Useful for initial explorations and characterizations
 - Not definitive enough for in-depth quantitative analyses of regolith mechanics
- With sufficient pre-flight testing, can inform on:
 - Volatile content
 - PSD
 - Composition
- Need sample piles above a given mass/volume because angle of repose is sample size-dependent

Site Characterization: Pressure-Sinkage

- Pressure-sinkage relationships inform on bearing capacity and tractive capabilities of the regolith
 - The ability to predict rover performance and safety factors in infrastructure development as a function of regolith properties is key
- Provides information on:
 - Relative compaction of local regolith for exploration and infrastructure development safety
 - Moisture and volatile content [Long-Fox et al., 2022]
- Models of pressure-sinkage
 - Bernstein (1913): $p = kz^n$
 - Bekker (1969): $p = \left(\frac{k_c}{b} + k_\phi\right) z^n$
 - Reece (1965): $p = (ck_c + \gamma bk_\phi) \left(\frac{z}{b}\right)^n$

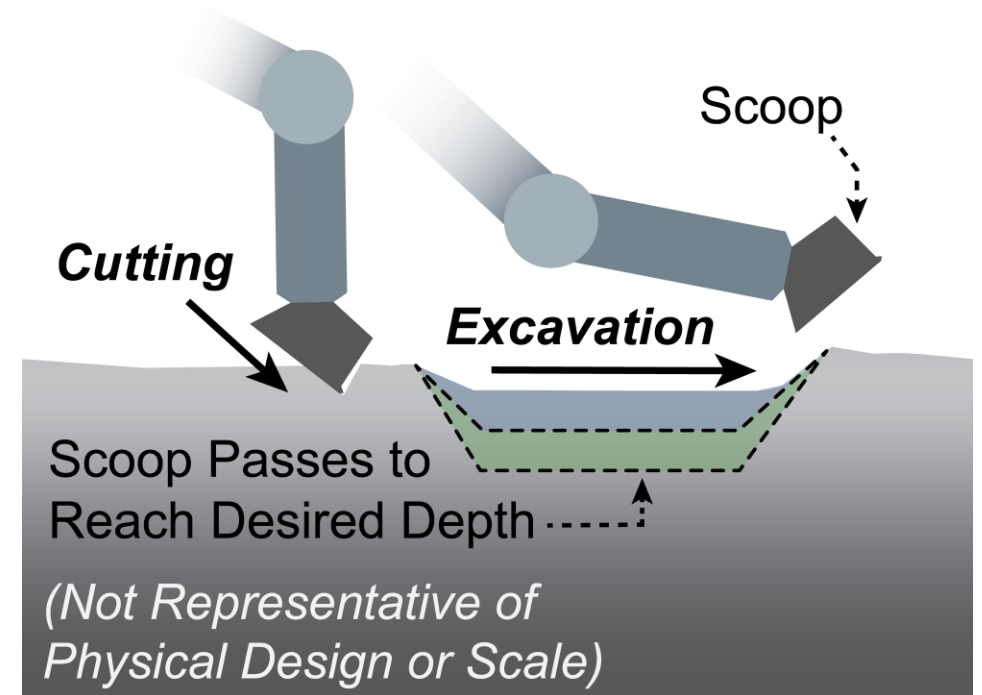

Site Characterization: Shear

- Shear strength is a fundamental property that determines bulk regolith behavior
 - Affected by relative state of compaction
 - Volatile content is expected to cause variations in shear strength
 - Sensitive to PSD and mineralogy
- Provides information on:
 - Traction
 - Load bearing capabilities
 - Material handling
- Mohr-Coulomb model of shear strength
 - $\tau_s = \sigma_n \tan(\phi) + c$

Site Characterization: Excavation

- Excavation is a convolution of horizontal and vertical forces acting on the regolith
 - Shear
 - Compression
- Forces required for excavation are a function of many material properties (e.g., density, porosity, cohesion, frictional constants,...)
- Desirable to be able to estimate material properties during excavation
 - Will allow adaption to changing regolith conditions

Excavation: Analytical Modeling

- COLDArm excavation data being modeled with simple analytical models (2D Reece's Fundamental Equation of Earthmoving – Reece, 1964)
- Estimating relevant properties of materials being excavated:
 - Cohesion (c)
 - Angle of internal friction (ϕ)
 - Shear plane failure angle (β)
 - Angle of external friction (δ)
- Markov Chain Monte Carlo (MCMC) for parameter estimations and F-tests for 2σ confidence intervals

$$F = w [cdN_c + \gamma d^2 N_\gamma + QdN_q]$$

w is scoop width

d is cutting depth

N_c, N_γ, N_q are dimensionless "N factors"

Q is surcharge load

Modified from McKyes (1985)

Excavation: Analytical Modeling

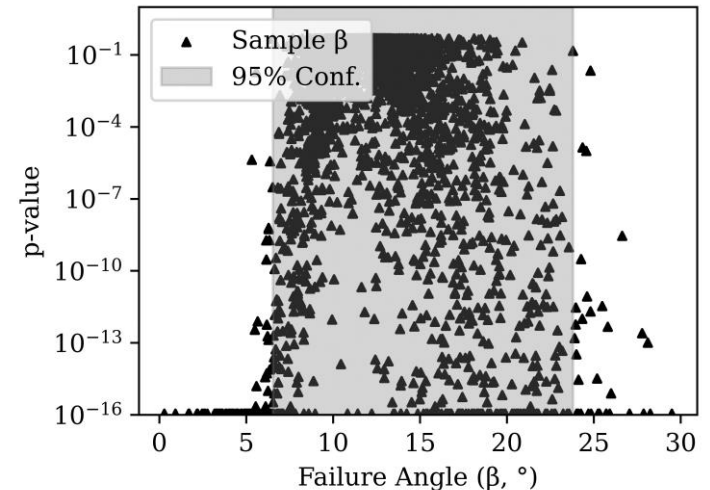

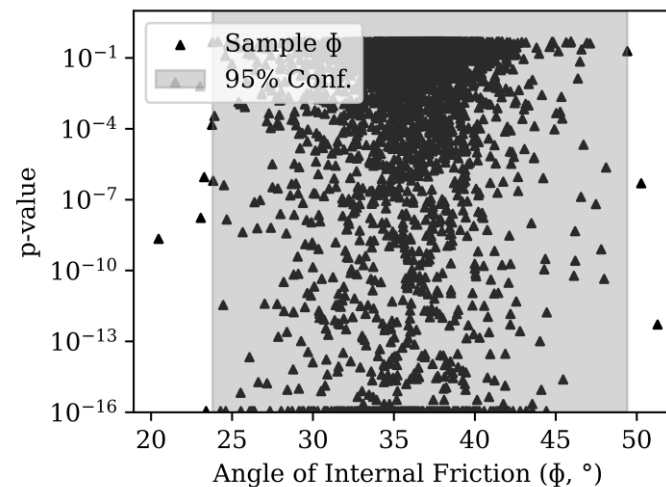

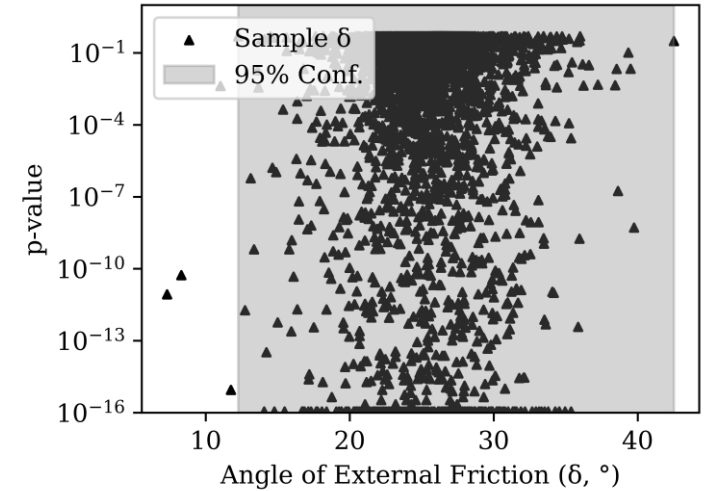

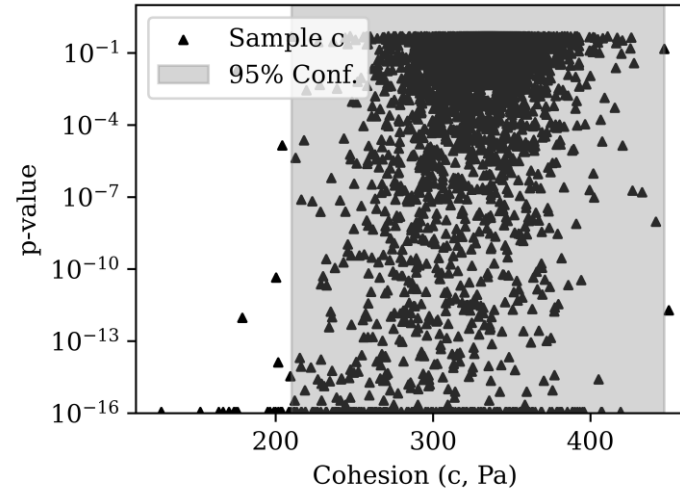

- COLDArm excavation testing starting late Summer 2023
- Recovery Test
 - Generate synthetic data using Reece's Fundamental Equation of Earthmoving with known input parameters (10% Gaussian noise added)
 - Run MCMC model to see if algorithm can predict synthetic data
 - 10 adaptations of 1,000 samples each to "home in" on best-fit set of parameter values
 - Reece's FEE provides a suitable first-order set of parameter estimations

Parameter	Input	Predicted ($\pm 2\sigma$)	Error (%)
c (Pa)	311.00	$335.14 \pm \begin{matrix} 111.80 \\ 125.01 \end{matrix}$	7.76
φ ($^\circ$)	35.00	$37.55 \pm \begin{matrix} 11.88 \\ 13.75 \end{matrix}$	7.29
β ($^\circ$)	10.00	$11.92 \pm \begin{matrix} 11.88 \\ 5.38 \end{matrix}$	19.20
δ ($^\circ$)	25.00	$26.27 \pm \begin{matrix} 16.24 \\ 14.02 \end{matrix}$	5.08
N_c	4.74	$4.45 \pm \begin{matrix} 1.08 \\ 0.80 \end{matrix}$	6.12
N_γ	3.34	$3.22 \pm \begin{matrix} 0.98 \\ 0.89 \end{matrix}$	3.59
N_ρ	6.67	$6.44 \pm \begin{matrix} 1.96 \\ 1.77 \end{matrix}$	3.45

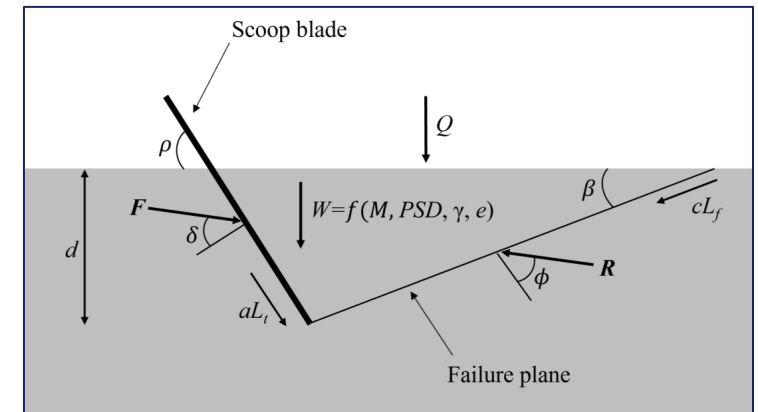

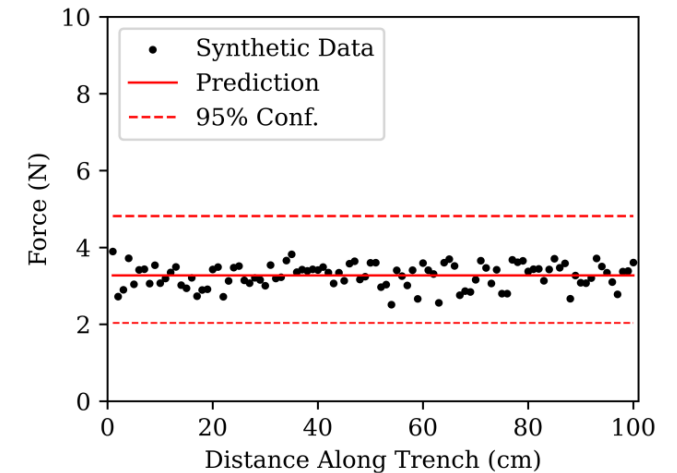

Excavation: Analytical Modeling

Parameter	Input	Predicted ($\pm 2\sigma$)	Error (%)
c (Pa)	311.00	$335.14 \pm \begin{matrix} 111.80 \\ 125.01 \end{matrix}$	7.76
φ ($^\circ$)	35.00	$37.55 \pm \begin{matrix} 11.88 \\ 13.75 \end{matrix}$	7.29
β ($^\circ$)	10.00	$11.92 \pm \begin{matrix} 11.88 \\ 5.38 \end{matrix}$	19.20
δ ($^\circ$)	25.00	$26.27 \pm \begin{matrix} 16.24 \\ 14.02 \end{matrix}$	5.08
N_c	4.74	$4.45 \pm \begin{matrix} 1.08 \\ 0.80 \end{matrix}$	6.12
N_γ	3.34	$3.22 \pm \begin{matrix} 0.98 \\ 0.89 \end{matrix}$	3.59
N_ρ	6.67	$6.44 \pm \begin{matrix} 1.96 \\ 1.77 \end{matrix}$	3.45

Excavation: Analytical Modeling

- Analytical models of excavation are overly simplistic
 - Homogeneity of materials
 - Flat free surface
 - Unrealistic tool geometry
 - Lack of environmental effects
 - Spurious empirical calibration coefficients
 - Unable to incorporate force reduction directly into model
- Need realistic models that can incorporate 3D distributions of material properties, uneven topography, and force reduction methods

Modified from McKyes (1985)

To fully describe a quantitative estimate, you need: 1) A measure of central tendency; 2) a sense of uncertainty; 3) rigorous analysis of assumptions and biases

Excavation: The Need for Force Reduction

- Need ways to reduce the reaction force needed for raw material acquisition during excavation due to challenging material properties and environment:
 - High cohesion and dilative nature of regolith
 - Reduced gravity (1/6 g on the Moon)
 - Launch mass budgets
- Experimental work in force reduction is showing good results, but none of these efforts have developed predictive capabilities
 - Vibration [Rezich et al., 2021]
 - Percussion [Green et al., 2013]

Image credit: Contour Crafting

Excavation: Numerical Modeling

- Numerical models allow for fewer simplifying assumptions compared to analytical models
 - CAD-based tool geometries allow testing of prototype hardware and allow for better mission planning
 - Arbitrary 3D domain geometries and material property distributions
 - Can prescribe various loadings such as vibration, percussion, and more
 - Multiphysics
- Finite element models (FEMs)
 - Continuum-based
 - Coupled Eulerian-Lagrangian treats regolith as a highly deformable solid being manipulated by a rigid tool
 - Often used in modeling soil-tool and soil-wheel interactions on Earth [Tagar et al., 2015]
- Discrete element models (DEMs)
 - Discontinuous, independently moving particles
 - Represents regolith as individual grains interacting with each other and tools/wheels
 - Becoming more common, but granular mechanics is extremely complex and hence difficult to describe computationally.

Excavation: Numerical Modeling

- FEMs are established, well-understood formulations that have been applied to modeling of terrestrial geological media in multiple fields for many years
- The representation of granular regolith as a solid or fluid-like material is inaccurate, but may capture bulk behavior suitably
 - What are the limitations of this approximation of net mechanical behavior specifically in the lunar case?

From Tagar et al. (2015)

Excavation: Numerical Modeling

- DEMs are computationally complex and the fledgling field of granular mechanics is still ill-resolved compared to the solid and/or fluid-like mechanics of FEMs
 - Difficult to fully capture all the physics [Schmulevich, 2010]
 - Different simulations require different material property calibrations- no reliable methods to determine which
 - Very computationally expensive
 - Do not handle wide PSDs well
 - Particle size distribution is the most important aspect of regolith for simulants to replicate [Sibille et al., 2006]
 - Planetary regolith generally has PSDs that span 7 or 8 orders of magnitude...

From Coetzee et al. (2017)

Future Work and Products

- Collect COLDArm excavation data (no force reduction)
 - Ingest into analytical models for parameter estimations → first-pass approximations of physical properties during excavation
 - Provides baseline data
- Develop percussive and vibratory excavation testing hardware
 - COLDArm scoop
 - Surveyor replica scoop
- Develop experiment arrays and perform experiments to collect data
 - Compare force reduction methodologies
 - Compare modeling methods (analytical vs. FEM vs. DEM)
- Develop and calibrate FEMs and DEMs
 - Statistically compare efficiency and accuracy of calibrated model predictions relative to experimental data
 - Calibration workflows and calibrated models will be new tools we can use to plan safe and efficient excavation operations planning
